

Document	Project Documentation Format
Project Name	Auto Ticket Classification using Flow Designer
Date	03 October 2026
Team ID	6ab8f5efc23107aaaa7325ec

Project Documentation

1. Introduction

- Project Title: Auto Ticket Classification using Flow Designer
- Team Members: Team ID 6ab8f5efc23107aaaa7325ec (roles: Developer, Process Owner, Tester, Manager)

2. Project Overview

- Purpose: Eliminate slow and inconsistent manual ticket triage by automatically classifying and routing tickets using Flow Designer.
- Features: Hybrid Rules + AI classification, confidence-based routing, agent feedback loop, full auditability, near real-time performance.

3. Architecture

- Orchestration: Flow Designer (low-code)
- Intelligence: Decision Tables (Rules) + AI Classification Model (Predictive Intelligence / AI Builder / optional external LLM)
- Data: Ticket/Incident table + Classification Audit Log + Feedback store
- UI: Existing Service Portal (End User) + Agent Workspace (Agent) – no new frontend required
- Integration: Optional REST / Integration Hub for external AI

4. Setup Instructions

- Prerequisites: Platform instance with Flow Designer, required tables, and (if used) AI classification capability enabled.
- Installation: Import / create the Flow, Decision Tables, system properties (confidence threshold), and audit table. Configure assignment groups and notification rules.
- No separate client/server Node.js setup is required – solution runs natively on the platform.

5. Folder / Component Structure

- Flow: Main classification flow (trigger, extract, classify, decide, update, log)
- Decision Tables: Keyword / category rules
- System Properties: Confidence threshold, enable/disable flags
- Audit Log table: Stores every classification decision
- Feedback mechanism: Correct/Incorrect action on ticket form

6. Running the Application

- Create a new ticket (or Incident) in the platform.
- Flow triggers automatically on record creation.
- Classification result appears on the ticket within seconds.
- No separate npm start commands – platform-managed execution.

7. API / Integration Points

- Internal: Platform record APIs and Flow actions.
- Optional External: REST call to AI classification endpoint (request: ticket text; response: category, priority, group, confidence, explanation).

8. Authentication & Authorization

- Uses platform RBAC / ACLs.
- Flow runs under a controlled service account with least privilege.
- Agents need normal ticket write access; Admins need Decision Table and property access.

9. User Interface

- End User: Existing Service Portal ticket form.
- Agent: Agent Workspace – classification fields, confidence, explanation, override and feedback controls.
- Manager: Optional dashboard for volume, confidence and override metrics.

10. Testing

- Unit / functional testing of Flow paths (rules, AI, fallback).
- UAT with real agents (see UAT Report).
- Performance testing under load (see Performance Testing documents).

11. Known Issues

- AI accuracy depends on quality of training / historical data.
- Very vague tickets will more frequently go to Manual Review (by design).

12. Future Enhancements

- Continuous model retraining from agent feedback
- Multi-language classification
- Attachment / image-based classification
- Automated bulk re-classification of backlog tickets
